Standard Search Problems

- A path from the start to the goal state is the solution.
- Paths have costs (or depths).
- Heuristics provide **problem-specific** guidance.
- State is a "black box", arbitrary data structure
- Goal test can be **any** function over states.

Route finding problem solved as a search problem

Constraint Satisfaction Problems (CSPs)

- CSP
 - A set of variables {X₁, X₂, ..., X_n) to which values (d₁, d₂, ..., d_n) from a domain D can be assigned.
- Solution
 - A complete variable assignment that is consistent (satisfies all the given constraints).
- States
 - Explicitly represented as variable assignments
- Goal test:
 - The set of constraints specifying allowable combination of values for subset of variables.

Example: Map Coloring

- Variables: WA, NT, Q, NSW, V, SA, T
- Domains: D = {red, green, blue}
- Constraints: adjacent regions must have different colors

Implicit: $WA \neq NT$

Explicit: $(WA, NT) \in \{(red, green), (red, blue), \ldots\}$

 Solutions are assignments satisfying all constraints, e.g.:

{WA=red, NT=green, Q=red, NSW=green, V=red, SA=blue, T=green}

Constraint Graph

- Binary constraint satisfaction problem
 - Each constraint relates (at most) two variables
- Binary constraint graph
 - Nodes are variables
 - Arcs show constraints
- General-purpose CSP solvers make use of the graph structure to speed up search.
 - E.g., Tasmania is an independent subproblem.

Example: Sudoku

Variables: Each (open) square Domains: {1, 2, ..., 9} Constraints:

9-way alldiff for each column9-way alldiff for each row9-way alldiff for each region

Example: Scheduling

An example of a manually prepared roster of persons assigned to shifts/rooms.

Nurse Scheduling Problem

- I set of nurses
- T discrete time horizon
- A set of activities
- cover constraints C_t / day t
- working rules \mathcal{R}_i / nurse i

28 days N night, M morning, E evening, R rest between 2 and 3 nurses at night at least 2 mornings a week

Types of Constraints

- Varieties of Constraints
 - Unary constraints involve a single variable (equivalent to reducing domains), e.g.:

 $SA \neq green$

- Binary constraints involve pairs of variables, e.g.: $SA \neq WA$
- Higher-order constraints involve 3 or more variables: e.g., sudoku constraints
- Preferences (soft constraints):
 - E.g., red is better than green
 - Often representable by a cost for each variable assignment
 - Gives constrained optimization problems

Solving CSPs

- Standard search formulation of CSPs
- States: values assigned so far (partial assignments)
 - Initial state: the empty assignment, {}
 - Successor function: assign a value to an unassigned variable
 - Goal test: the current assignment is complete and satisfies all constraints

Standard Search

One stage of successor generation. Select variable Q and try Red, Blue or Green values.

- Enumerate all assignments to variables. Create the entire tree.
- Check all the constraints at the end. Goal can be checked at the bottom of the tree.
- Can use a search method like DFS.

Problem with a direct DFS search?

- Testing the constraints at the end, only then we know that the goal has been attained.
- Do we need to wait till all variables assigned if we already know that the assignment is failing.
- Can we test incrementally and detect failures earlier than the complete assignment?

Backtracking Search over Assignments

• Search component

- At each step, consider assignments to a single variable
- Variable assignments are commutative (we can pick the order)
- I.e., [WA = red then NT = green] same as [NT = green then WA = red]

Inference or Constraint Checking

- Can we check constraints incrementally instead of all at the end?
 - Incremental "goal test". Check constraints as the variable is assigned.
 - I.e. only assign values to variables which do not conflict previous assignments.
- Some computation is involved in checking constraints.

Backtracking Search

- Depth-first search with *incremental variable assignment* and *constraint checking on the go*.
- Back track as soon as a failure is detected.

Backtracking Search

• Informally,

.

- Pick a variable to assign.
- Pick an assignment for the variable.
- Check if all the constraints are satisfied.
- If the constraints are not satisfied, then try a different assignment.
- If no assignments left, need to back track.
- If the assignment is complete, then we have a solution.

Generate successors by selecting variables and values. Incrementally check the violation of constraints (backtrack when necessary).

Backtracking Search: Pseudocode

function BACKTRACKING-SEARCH(csp) returns solution/failure
return RECURSIVE-BACKTRACKING({ }, csp)

function RECURSIVE-BACKTRACKING(assignment, csp) returns soln/failure if assignment is complete then return assignment $var \leftarrow SELECT-UNASSIGNED-VARIABLE(VARIABLES[csp], assignment, csp)$ for each value in ORDER-DOMAIN-VALUES(var, assignment, csp) do if value is consistent with assignment given CONSTRAINTS[csp] then add {var = value} to assignment result \leftarrow RECURSIVE-BACKTRACKING(assignment, csp) if result \neq failure then return result remove {var = value} from assignment return failure

Backtracking = DFS + variable-ordering + fail-on-violation

Backtracking Search

function BACKTRACKING-SEARCH(csp) returns solution/failure
return RECURSIVE-BACKTRACKING({ }, csp)

function RECURSIVE-BACKTRACKING(*assignment, csp*) **returns soln**/failure **if** *assignment* **is complete then return** *assignment*

 $var \leftarrow \text{SELECT-UNASSIGNED-VARIABLE}(\text{VARIABLES}[csp], assignment, csp)$

for each value in Opper Domain Values (var assignment each de

for each value in ORDER-DOMAIN-VALUES(var, assignment, csp) do

if value is consistent with assignment given CONSTRAINTS [csp] then

add $\{var = value\}$ to assignment

 $result \leftarrow \text{Recursive-Backtracking}(assignment, csp)$

if $result \neq failure$ then return result

remove $\{var = value\}$ from assignment

return failure

How to order the variables during backtracking search?

Ordering Variables

- Most Constrained Variable (Minimum Remaining Values)
 - When you have multiple variables to assign, then choose the variable with the *fewest* remaining legal values in its domain
 - A CSP solution must have an assignment for <u>all variables</u>.
 - Try the variables likely to fail early rather than late. Fail fast.

After assigning WA = R, the variables NT and SA have two legal values where as Q, NSW, V and T have three legal values. Prefer selecting NT or SA over the other remaining variables.

Degree Heuristic

- Take the case of picking the first variable to assign.
 - Minimum Remaining Values Heuristic does not help in the first variable. All have the same number of legal values in the domain.
 - In general, how to break ties among MRV variables?
- Degree Heuristic
 - Select the variable involved in the largest number of constraints on other unassigned variables.
 - Why?
 - This value reduces possible values for others. In effect, reduces branching factor.

Backtracking Search

function BACKTRACKING-SEARCH(csp) returns solution/failure
return RECURSIVE-BACKTRACKING({ }, csp)

function RECURSIVE-BACKTRACKING(assignment, csp) returns soln/failure

if assignment is complete then return assignment

 $var \leftarrow \text{Select-Unassigned-Variable}(\text{Variables}[csp], assignment, csp)$

for each value in ORDER-DOMAIN-VALUES (var, assignment, csp) do

if value is consistent with assignment given CONSTRAINTS[csp] then

add $\{var = value\}$ to assignment

 $result \leftarrow \text{Recursive-Backtracking}(assignment, csp)$

if $result \neq failure$ then return result

remove $\{var = value\}$ from assignment

return failure

Ordering Values

Least Constrained Value

Given a variable choose a value that rules out the fewest values in the remaining unassigned variables.

- Leave maximum flexibility for subsequent assignments.
- We only need one value (assigned to a variable) so that the constraints are satisfied. Look for most likely solutions first. Fail <u>last</u>.

Consider the case where: WA = R and NT = G.

Next, we pick Q for an assignment. Options are Q=R or Q=B.

Examine effect on SA (Q=Red is a better option) as it leaves a possible assignment instead of Q=Blue.

Solving CSPs: Improving Efficiency

- Which variable should be assigned next?
- In what order should its values be tried?
- Can we detect inevitable failures early?
- Can we take advantage of the problem structure?

<pre>function BACKTRACKING-SEARCH(csp) returns a solution, or failure return BACKTRACK({ }, csp)</pre>						
function BACKTRACK(assignment, csp) returns a solution, or failure						
if assignment is complete then return assignment						
$var \leftarrow SELECT-UNASSIGNED-VARIABLE(csp)$						
for each value in ORDER-DOMAIN-VALUES(var, assignment, csp) do						
if value is consistent with assignment then						
add { $var = value$ } to assignment						
$inferences \leftarrow INFERENCE(csp, var, value)$						
if inferences \neq failure then						
add inferences to assignment						
$result \leftarrow BACKTRACK(assignment, csp)$						
if $result \neq failure$ then						
return result						
remove $\{var = value\}$ and <i>inferences</i> from <i>assignment</i>						
return failure						

Inference/Filtering: Forward Checking

- Basic Idea: Track domains for unassigned variables and eliminate values that violate constraints with existing assignments. Propagate information from assigned to unassigned variables linked with a constraint.
- Forward Checking: When a variable X is assigned, check the unassigned variable Y connected to X by a constraint. Delete from Y any value that is inconsistent with the value assigned for X.

Problem with Forward Checking

- Forward Checking propagates information from assigned to unassigned variables. No propagation <u>between</u> unassigned variables.
- Only 1-step look ahead, does not examine all future implications of the current assignment.

Arc Consistency

- A directed arc $X \to Y$ is "consistent" iff
 - for every value x of X, there exists a value y of Y, such that (x, y) satisfies the constraint between X and Y
- ${\scriptstyle \bullet}$ Remove values from the domain of X to enforce arc-consistency
- Arc consistency detects failures earlier

Takeaway

 If the domain values at the head (Y) change when assigned, then we need to check if the values in the tail (X) are still consistent with the assignment to Y. If not, then remove the values for X that are inconsistent, thereby making the arc X -> Y "arc consistent".

Enforcing Consistency of a Single Arc

An arc X → Y is consistent iff for every value for x (the "tail" of the arc) there is some value y (the "head" of the arc) which could be assigned without violating a constraint.

Remember: Always delete the domain value from the "tail" of the arc.

Enforcing Arc Consistency for the Entire CSP

• Ensure that **all** arcs in the constraint graph are consistent:

• Take away

- If X loses a value in its domain, the neighbors of X (arcs coming in) need to be **re-examined** for consistency.
- Arc consistency detects failure **earlier** than forward checking.
- Forward checking was 1-step look ahead. Arc consistency further examines implications.
- If no values left in the domain of a variable, then do not continue and backtrack as the CSP does not have a solution

AC-3: Enforcing Arc Consistency in a CSP

Mackworth, 1977

Maintain a gueue of arcs	function AC-3(csp) returns false if an inconsistency is found and true otherwise inputs: csp, a binary CSP with components (X, D, C) local variables: queue, a queue of arcs, initially all the arcs in csp
Obtain an ara	while queue is not empty do
Obtain an arc	$(X_i, X_j) \leftarrow \text{REMOVE-FIRST}(queue)$
Γ	if REVISE(csp, X_i, X_j) then
If the domain of X _i (tail) changes	if size of $D_i = 0$ then return false
due to X _j (head) then, add all the	for each X_k in X_i .NEIGHBORS - $\{X_j\}$ do
edges coming into X _i from the	add (X_k, X_i) to queue
X _k . (Done by inserting X _k , X _i)	return true
	function REVISE(<i>csp</i> , X_i , X_j) returns true iff we revise the domain of X_i <i>revised</i> \leftarrow <i>false</i> for each x in D_i do
Enforce arc consistency	if no value y in D_j allows (x,y) to satisfy the constraint between X_i and X_j then
between X _i (tail) -> X _j (head).	delete x from D_i
Checking if due to assignment	$revised \leftarrow true$
for X _j is adjustment needed for X _i ?	return revised

Runtime: O(n²d³) [n² edges x d² time in consistency x d arc insertions (only domain reduction triggers insertion of an edge in the queue)]

Backtracking Search (with Inference)

• Run Forward Checking or Arc Consistency.

- Also called interleaving search and inference.
- Polynomial time
- We will still back track at times as AC-3 cannot detect all the inconsistencies (detecting all inconsistencies is NP-hard).

function BACKTRACKING-SEARCH(csp) returns a solution, or failure **return** BACKTRACK({ }, *csp*) function BACKTRACK(assignment, csp) returns a solution, or failure if assignment is complete then return assignment $var \leftarrow SELECT-UNASSIGNED-VARIABLE(csp)$ for each value in ORDER-DOMAIN-VALUES(var, assignment, csp) do if value is consistent with assignment then add {var = value} to assignment $inferences \leftarrow INFERENCE(csp, var, value)$ if inferences \neq failure then add inferences to assignment $result \leftarrow BACKTRACK(assignment, csp)$ if result \neq failure then return result remove $\{var = value\}$ and *inferences* from *assignment* return failure

Arc Consistency: Limitation

- After enforcing arc consistency:
 - Can have one solution left
 - Can have multiple solutions left
 - Can have no solutions left (and not know it)

- This CSP has a consistent assignment (see top figure).
- Consider the second assignment, arc consistency is established but there is no overall solution in this case (see below figure).

K-Consistency

- Increasing degrees of consistency
 - 1-Consistency (Node Consistency): Each single node's domain has a value which meets that node's unary constraints
 - 2-Consistency (Arc Consistency): For each pair of nodes, any consistent assignment to one can be extended to the other
 - K-Consistency: For each k nodes, any consistent assignment to k-1 can be extended to the kth node.
 - Higher k more expensive to compute.
- k=2 case is arc consistency.
 - In our example, arc consistency was enforced (K=2) but path consistency (K=3) was not. The overall inconsistency could not be detected with K=2.

Exploiting Problem Structure

General idea: Some CSP structures are easy to solve. Either find and exploit that structure or perform reductions to simplify the problem.

- Independent subproblems are identifiable as connected components of constraint graph
 - Example: Tasmania and mainland do not interact
 - Decomposing a graph of n variables into subproblems of only c variables simplifies the problem.

Tree-structured CSPs

- Some CSP structures are easier to solve
- Theorem: if the constraint graph has no loops, the CSP can be solved in O(n d²) time
- Compare to general CSPs, where worst-case time is O(dⁿ)

Tree-Structured CSPs

- Algorithm for tree-structured CSPs
 - Topological sort: Choose a root variable, order variables so that parents precede children

- Remove backward: For i = n : 2, apply Make-Arc-Consistent (Parent(X_i), X_i)
- Assign forward: For i = 1 : n, assign X_i consistently with Parent(X_i) by picking any consistent value from the domain.

Improving Structure

- Overall idea
 - If we can handle the instantiation of certain variables, then the remaining problem can be simplified.
 - Conditioning: instantiate a variable, prune its neighbors' domains and solve the residual graph
 - The residual graph is easier to solve as it is tree structured.
- Cutset conditioning
 - Find a subset of variables S, such that the remaining constraint graph becomes a tree after the removal of S (S is a cycle cut set).
 - Instantiate (in all ways) a set of variables such that the remaining constraint graph is a tree.
 - Remove from the domains of the remaining variables any values that are inconsistent with the assignment for S

Cutset Conditioning

Note: branching on the number of ways to instantiate the cut set variables.

Finding the "optimal" cutset is not easy (in general NP-hard). Easier if we know about the problem structure.
