1. Instead of defining the terminating condition of a Turing machine using final states, it is possible to define it using the condition of the head falling off the leftmost cell. Show that the two classes of machines are equivalent, i.e., we can simulate one by the other.

2. For any arbitrary TM $M$, we want to show that it can be simulated by another Turing Machine with tape alphabet restricted to $\{0, 1, B\}$. For this, we would like to encode the tape alphabet of $M$ using some appropriate $\{0, 1, B\}^\ell$.
   (i) Assuming the input alphabet $\Sigma = \{0, 1\}$, show how to encode the initial input $w \in \Sigma^*$
   (ii) Show how to emulate the $\delta$ of $M$ given the encoded input.
   Discuss if it is possible to restrict to only two tape symbols. In this case you do not have to address the initial encoding of input and assume that is provided on the tape.

3. Show that a $T(n)$ time bounded $k$ tape Turing machine can be simulated by a 1 tape machine in $O(T^2(n))$ steps.
   Use this result to show how a Random Access Machine can be simulated by a 1 tape TM incurring at most a polynomial overhead. The RAM model is a logarithmic cost RAM model (not uniform cost).

4. Show that every TM can be simulated by an off-line TM having one storage tape with two symbols 0 (blank) and 1 (non-blank). Further this machine can overwrite a 0 by 1 but cannot overwrite a 1 by a 0.

5. Show that a TM that cannot write, accepts exactly the class of regular languages.
   Hint: Simulate such a TM by an NFA using the notion of crossing sequences.

6. Show formally that the halting problem is undecidable - Given a string $< M, w >$, is there an algorithm to decide if $M$ halts on $w$ (does not necessarily accept $w$)?

7. Given input $< M_1, M_2 >$, is the problem $L(M_1) \cap L(M_2) \neq \phi$ decidable? Justify. ($M_1, M_2$ are codes of TM).

8. The proof of Rice’s theorem exploits the result that $L_u$ (universal language) is non-recursive. Given Rice’s theorem, can you prove that $L_u$ is not recursive?

9. Are the following problems decidable?
   (a) Given a TM $M$, whether $M$ ever writes a specific non-blank symbol when started on an empty tape.
   (b) Given a TM $M$, whether there is a $w$ such that $M$ enters each of its states during the computation on $w$.
   (c) Given a TM $M$ and an input $w$, does the head ever visit the $B$-th square for a given integer $B$.

10. Show that for every r.e. language $L$, there is an infinite recursive language $L'$, where $L' \subset L$.
    Conversely, is it true that for every infinite recursive language, there is a subset that is not recursive?
